A versatile disaster recovery platform The program combines the power of multiple backup and restore technologies in order to speed up the process of recovering important data in minutes. The idea behind the product is to offer an alternative to tedious manual backups, providing all that is needed for automation through scheduled tasks. It helps minimize downtime and avoid disaster by easily recovering individual data files/folders, Exchange email messages, SharePoint documents or complete Windows systems in minutes, regardless of supported hardware, virtual environments, or remote locations. Centralized management solution Administrators can carry out restorations from bare metal with a low risk of encountering errors and with significantly fewer efforts than in more traditional approaches. With the aid of the off-site copy feature, restore points are transferred to an outer location, such as a FTP server or an external drive. Veritas System Recovery is built on a scalable platform where the management of the servers and clients is done in a professional manner. A central server can handle thousands of clients, allowing administrators to deploy and control policies, installations, and backups remotely. Other tasks that can be performed through the central component include recovery monitoring, environment tracking, as well as maintenance for both Linux and Windows servers. An industry-leading product Veritas System Recovery consists of a powerful set of tools that makes sure important data is always kept under supervision and backed up on a regular basis. Backups are efficiently compressed, which makes restoration operations faster. "Do you want full or incremental backups?" Reduce downtime. Ensure data consistency. Restore data in a fast and reliable way. Each of these are treated at the individual backup level. If you do not want full backups at a specific point in time, you have options to work around it, but they will cause you problems sooner or later. I generally find that the best approach is to do full backups on a regular basis using a snapshot (i.e., dd or DBAN) and then take periodic incremental backups with my preferred backup tool (i.e., rdiff-backup or you can use to create an image). If you want to avoid downtime because of a backup failure, you can set up your backup tool to create a disk image (or use DRBD (The above techniques are usually better than doing incremental backups because they are more efficient and have fewer metadata problems (i.e., they are easier to recover from). That said, you are better off just having full backups with a simple rotation scheme than doing incremental backups and not having any backups.
